

(a) Natural Image Model Merging

Generic visual evidence is broadly shared across isolated natural clients.

(b) Medical Image Model Merging

Merging partial experts collapses the global prediction.

Observation 1: Diagnostic evidence is fragmented

Clients only learn the diagnosis classes in their own hospitals.

Problem 1: Partial coverage triggers prediction collapse

Most test images are assigned to one dominant diagnosis

Observation 2: Medical images follow a long-tailed distribution

The true medical test set is naturally long-tailed: common diagnoses dominate.

Problem 2: A collapsed model gets a fake-high accuracy

High raw ACC
but poor multi-class discrimination
